# catena-Poly[[[bis(thiourea- $\kappa$ S)cadmium]-di- $\mu$-thiocyanato- $\left.\kappa^{2} N: S ; \kappa^{2} S: N\right]$ dihydrate] 

Anna Mietlarek-Kropidłowska* and Jaroslaw Chojnacki<br>Department of Inorganic Chemistry, Chemical Faculty, Gdansk University of Technology, 11/12 G. Narutowicza Str., 80-233 Gdańsk, Poland<br>Correspondence e-mail: anna.mietlarek-kropidlowska@pg.gda.pl

Received 18 June 2012; accepted 3 July 2012
Key indicators: single-crystal X-ray study; $T=293 \mathrm{~K}$; mean $\sigma(\mathrm{N}-\mathrm{C})=0.003 \AA$; $R$ factor $=0.028 ; w R$ factor $=0.062$; data-to-parameter ratio $=26.7$.

The title compound, $\left\{\left[\mathrm{Cd}(\mathrm{NCS})_{2}\left(\mathrm{CH}_{4} \mathrm{~N}_{2} \mathrm{~S}\right)_{2}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}\right\}_{n}$, forms a one-dimensional chain parallel to the $a$ axis, caused by the presence of the bridging thiocyanate groups. Two solvent molecules per complex are present in the lattice. The $\mathrm{Cd}^{\mathrm{II}}$ ion is situated on an inversion centre and is coordinated in a distorted octahedral fashion by two N and two S atoms from four thiocyanate ligands and by two S atoms from two thiourea molecules. Weak $\mathrm{O}-\mathrm{H} \cdots \mathrm{S}, \mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ and $\mathrm{N}-$ $\mathrm{H} \cdots \mathrm{N}$ interactions reinforce the structure.

## catena-Poly[[[bis(thiourea- $\kappa$ S) cadmium]-di- $\mu$-thiocyanato- $\left.\kappa^{2} N: S ; \kappa^{2} S: N\right]$ dihydrate]

## Anna Mietlarek-Kropidłowska and Jaroslaw Chojnacki

## S1. Comment

The interest in the coordination compounds possessing simultaneously thiourea and thiocyanato ligands dates back to the 1950s (e.g. Nardelli et al., 1957) when the nature of coordination compounds formed by divalent cations ( $M=\mathrm{Mn}$, Co, $\mathrm{Ni}, \mathrm{Cd}, \mathrm{Pb}$ ) and organic molecules containing sulfur was extensively studied. Besides the polymeric catena-poly[bis(thio-cyanato- $\kappa N$ ) bis $\left(\mu\right.$-thiourea- $\kappa^{2} S: S$ )cadmium(II)] (Wang et al., 2002), also structures of four other complexes with thiourea derivatives of $\left[\mathrm{Cd}(\mathrm{SCN})_{2}(\mathrm{TU})_{2}\right]_{\mathrm{n}}$ type, where $\mathrm{TU}=$ ethylenethiourea (Cavalca et al., 1960), $N, N^{\prime}$-diphenylthiourea (Zhu et al., 2000), $N$-phenylthiourea (Yang et al., 2001; Ahmad et al., 2008) or 1,3-dimethyl-2(3H)-imidazolethione (Williams et al., 1992), can be found. The interest in these compounds is related either with their non-linear optical properties (Yuan et al., 1997) or with the possibility to use them as single-source precursors of semiconducting materials based on CdS (Krunks et al., 1997; Amutha et al., 2011). Moreover, the use of SCN ligands, with bridging abilities, may lead to intriguing architectures and topologies, often generating one-dimensional chains (Machura et al., 2011). It was the reason why, during our studies on the new molecular precursors (Kropidłowska et al., 2008), we have turned our attention to systems of this type now and we have obtained a new complex containing thiourea and thiocyanato ligands connected to cadmium center.

The cadmium atom in catena-Poly[[[bis(thiourea- $\kappa S$ )cadmium]-di- $\mu$-thiocyanato- $\left.\kappa^{2} N: S ; \kappa^{2} S: N\right]$ dihydrate] is located at the inversion center and is octahedrically coordinated by two S atoms and two N atoms from four thiocyanate groups as well as by two S atoms from thiourea molecules. The neighbouring $\mathrm{Cd}^{\mathrm{II}}$ ions are bridged by two $\mu-\mathrm{SCN}-\kappa^{2} N: S$ ligands, thus forming eight-membered ring of $[\mathrm{Cd}-\mathrm{SCN}]_{2}$ type with the $\mathrm{Cd} \cdots \mathrm{Cd}$ distance of $5.853 \AA$, which is close to the values observed in other bridged systems (Machura et al., 2011). These units form one-dimensional chains of slightly distorted edge-shared Cd-centered octahedra along the [100] crystallographic direction. The $\mathrm{Cd}-\mathrm{SiCd}-\mathrm{N}$ distances are typical for cadmium(II) thiocyanate complexes. The IR spectra clearly show the presence of the thiocyanato groups (with the maxima of $v_{\mathrm{CN}}$ absorption at $2078 \mathrm{~cm}^{-1}$ ).
In the structure of $\left[\left[\mathrm{Cd}\left\{\mathrm{SC}\left(\mathrm{NH}_{2}\right)_{2}\right\}_{2}(\mathrm{SCN})_{2}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}\right]_{\text {n }}$, several weak interactions may be assumed, leading to the alternating arrangement of water and complex molecules. Each water molecule interacts with S or N atoms from the three neighboring polymeric chains. Thus, it can serve as a donor of a weak hydrogen bond to the sulfur atom from one of the thiourea moieties ( $\left.\mathrm{O} 1(\mathrm{H} 1 \mathrm{D})-\mathrm{S} 1^{\text {viii }}\right)$ in one chain, as well as to sulfur from one thiocyanato ligand (O1(H1C) —S2) in the other. The oxygen lone pairs act as acceptors towards $\mathrm{NH}_{2}$ groups from thiourea moieties located within the third chain (N2(H2B) -O1 ${ }^{\text {vii }}, \mathrm{N} 1(\mathrm{H} 1 \mathrm{~A})-\mathrm{O}^{\mathrm{v}}$, N2(H2A)—O1v). Finally, one "interchain" interaction, N1—H1B $\cdots \mathrm{N}^{\mathrm{i}}$, operates between $\mathrm{NH}_{2}$ and SCN groups.

## S2. Experimental

The reaction was carried out between 0.50 g cadmium(II) thiocyanate, $\mathrm{Cd}(\mathrm{SCN})_{2}$, and 1.34 g thiourea (molar ratio 1:8) which were dissolved in a small amount of water. The mixture was heated to $70^{\circ} \mathrm{C}$ and stirred using magnetic stirrer for 50 minutes and then left for crystallization at room temperature. After a few days two types of crystals appeared in the flask: needles $(0.2 \mathrm{~g})$ and blocks $(0.1 \mathrm{~g})$, which were mechanically separated under the microscope. The structure of needle-like crystals $\left[\mathrm{Cd}(\mathrm{SCN})_{2}\left\{\mu-\mathrm{SC}\left(\mathrm{NH}_{2}\right)_{2}\right\}\right]_{\mathrm{n}}\left(\mathrm{m} . \mathrm{p} .189^{\circ} \mathrm{C}\right)$ has been already described (Wang et al., 2002), while the block-like crystals appeared to be a new compound, crystallizing as diaqua solvate $\left[\left[\mathrm{Cd}\left\{\mathrm{SC}\left(\mathrm{NH}_{2}\right)_{2}\right\}_{2}(\mathrm{SCN})_{2}\right] .2 \mathrm{H}_{2} \mathrm{O}\right]_{\text {n }}$ (m.p. $187^{\circ} \mathrm{C}$ ). The product, when taken from the mother liquor and dried using the filter paper, changes - becomes opaque and finally takes the form of a powder (most probably because of the removal of the solvent molecules). IR spectra were recorded using Mattson Genesis II Gold spectrometer equipped with Momentum Microscope as detector.

## S3. Refinement

All $\mathrm{N} — \mathrm{H}$ atoms were placed in calculated positions and refined as riding on their carrier atoms with $\mathrm{N} — \mathrm{H}=0.86 \AA$ $\left(\mathrm{NH}_{2}\right)$ and $U_{\text {iso }}(\mathrm{H})=1.2$ times $U_{\text {eq }}(\mathrm{N})$. Solvent $\mathrm{O}-\mathrm{H}$ hydrogen atoms were found in the Fourier map and refined as constrained to: $\mathrm{O}-\mathrm{H}$ bond length of $0.80 \AA, \mathrm{H} 1 \mathrm{C}-\mathrm{H} 1 \mathrm{D}$ distance of $1.30 \AA$ and $U_{\mathrm{iso}}(\mathrm{H})=1.5$ times $U_{\text {eq }}(\mathrm{O})$ with the default uncertainties.

Figure 1
Molecular structure and atom-numbering scheme for $\left[\left[\mathrm{Cd}\left\{\mathrm{SC}\left(\mathrm{NH}_{2}\right)_{2}\right\}_{2}(\mathrm{SCN})_{2}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}\right]_{\mathrm{n}}$ with displacement ellipsoids drawn at $50 \%$ probability level. H atoms are represented as arbitrary circles. Symmetry codes: (i) x+1, y, z; (ii) $-\mathrm{x},-\mathrm{y}+1$, z; (iii) $-\mathrm{x}+1,-\mathrm{y}+1,-\mathrm{z}$.

Figure 2
Weak interaction present in the crystal structure of $\left[\left[\mathrm{Cd}\left\{\mathrm{SC}\left(\mathrm{NH}_{2}\right)_{2}\right\}_{2}(\mathrm{SCN})_{2}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}\right]_{\mathrm{n}}$ between the water and complex molecules (on the left). The arrangement of water and complex molecules in the crystal (on the right). Dashed lines denote the possible weak interactions.

## Special details

Experimental. CrysAlisPro, (Oxford Diffraction, 2008). Analytical numeric absorption correction using a multifaceted crystal model based on expressions derived by (Clark \& Reid, 1995).
Geometry. All s.u.'s (except the s.u. in the dihedral angle between two 1.s. planes) are estimated using the full covariance matrix. The cell s.u.'s are taken into account individually in the estimation of s.u.'s in distances, angles and torsion angles; correlations between s.u.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell s.u.'s is used for estimating s.u.'s involving l.s. planes.
Refinement. Refinement of $F^{2}$ against ALL reflections. The weighted $R$-factor $w R$ and goodness of fit $S$ are based on $F^{2}$, conventional $R$-factors $R$ are based on $F$, with $F$ set to zero for negative $F^{2}$. The threshold expression of $F^{2}>2 \sigma\left(F^{2}\right)$ is used only for calculating $R$-factors(gt) etc. and is not relevant to the choice of reflections for refinement. $R$-factors based on $F^{2}$ are statistically about twice as large as those based on $F$, and $R$ - factors based on ALL data will be even larger.
